

## Lab 7: Multiple Pages in React

In this lab, you will extend your existing React application to support multiple “pages” (through routes). Please, note that this lab will last **2 weeks**.

### 1. Define the Pages of your Application

Identify all the pages your application should be divided into, according to the requirements of your chosen exam topic. For each page, specify the following pieces of information in the README file present in your group repository:

- The **URL path**, following the best practices discussed in class.
- The **components** that will be rendered on the page.
- 

### 2. Enable Routing through React Router

Update your React application to support routing through React Router (<https://reactrouter.com>). Implement each of the pages you defined in the previous step, including the necessary components and route configuration.

In addition, design and implement a new page layout to be rendered when the user enters an **invalid URL**.
